Abstract Latinos have become the largest minority group in American postsecondary education, a majority of whom attend two- or four-year Hispanic-Serving Institutions (HSIs). However, little is known about labor market outcomes as result of attending these institutions. Using a unique student-level administrative database in Texas, and accounting for college selectivity, we examine whether attending an HSI influences labor market outcomes ten years after high school graduation for Latino students in Texas. We find no difference in the earnings of Hispanic graduates from HSIs and non-HSIs. This analysis represents one of the first to examine the labor market outcomes for Latino students in this sector of education accounting for critical factors that include a student's high school and community context.

Keywords Hispanic-serving institutions · HSIs · Wage returns · Labor market returns

The data for this study include restricted-use administrative records from the Texas Education Agency, the Texas Higher Education Coordinating Board, and the Texas Workforce Commission. The conclusions of this research do not necessarily reflect the opinions or official position of the Texas Education Agency, the Texas Higher Education Coordinating Board, the Texas Workforce Commission, or the state of Texas.

Introduction

It is a well-known fact that Latinos have become the largest minority group in the United States (Ennis et al. 2011).¹ A significant demographic shift also has occurred in the U.S. higher education population: with more than 2.4 million postsecondary students in 2012, Latinos have replaced Blacks as the largest minority group attending two- and four-year institutions (Fry and Lopez 2012; Krogstad and Fry 2014). As of 2013, 58.9% of Hispanic college students were attending two- or four-year Hispanic-Serving Institutions (HSIs), a category of institution that is accredited, grants degrees, and whose full-time-equivalent undergraduate enrollment is at least 25% Hispanic (Hispanic Association of Colleges and Universities 2015; Santiago and Andrade 2010; U.S. Department of Education 2009, 2013). These institutions, which are located primarily in areas with a high Latino demographic presence, such as the U.S. West, Southwest, and some parts of the Northeast, began to emerge officially in greater numbers in the 1980s. However, the HSI designation does not mean that an institution was founded specifically to promote the education of Hispanic students (Espino and Cheslock 2008; Harmon 2012), which contrasts with the Historically Black Colleges and Universities (HBCUs) founded in the mid-nineteenth century. While a number of institutions today can identify as an HSI due to a demographic tipping point (their student population becomes more than 25 percent Hispanic over time), most HSIs that demonstrate a formal commitment to serving Latino students do so through programming funded through federal policy specific to these institutions. This is done through programs tied to Title III and Title V funding focused on student success initiatives. The most recent program through Title V known as “Developing Hispanic Serving Institutions” has evolved over time, becoming more specific about funding objectives related to serving Latino students through the reauthorization of the 1998 and 2008 higher education acts (U.S. Department of Education 2013). HSIs nonetheless have not received much attention in terms of policy analysis, although their increasingly being the first-choice institution for a majority of Latino students highlights their importance in the Latino postsecondary trajectory (Benitez and DeAro 2004; Flores and Park 2013; Laden 2004; Núñez and Bowers 2011; Provasnik and Shafer 2004). In sum, HSIs educate a greater number of Latino students as a proportion of the college-going population than any other set of postsecondary institutions.

The number of Latinos enrolled in U.S. postsecondary institutions grew more than 240% from 1996 (728,000) to 2012 (2.4 M), far outpacing growth among Blacks (72%: 897,000–1.7 M) and Whites (12%: 6.2 M–7.2 M). While this unprecedented growth has received increasing attention, so has the value of the college degree (Krogstad and Fry 2014). While the cost to attend college has risen at an alarming rate in many states across the nation, the value of a college degree, particularly the four-year degree, has sustained its relevance in the 21st-century U.S. economy (Carnevale et al. 2010; Perna and Finney 2014). For example, Carnevale et al. (2010) estimate that the lifetime earnings of those with a four-year college degree will be \$1.6 million higher than those with only a high

¹ This study utilized the same definitional construction of the term “Hispanic” as is used by the 2010 U.S. Census. That is, an individual’s self-identification of Hispanic origin, regardless of race, triggers their inclusion in this group. While we use the terms “Latino” and “Hispanic” interchangeably, Hispanic is primarily used to be consistent with this nomenclature present in U.S. policy documentation and the federal higher education funding program serving this population: Hispanic-Serving Institutions.

school diploma; this amounts to more than a 191% difference in lifetime earnings between college and high school graduates. Moreover, those with an associate's degree or some college are likely to earn 26% more than high school graduates, who in turn can expect to earn 68% more than non-high school graduates.

In states where Latinos are already the majority minority group and the majority population in some school districts, the cost of not educating this population goes beyond the matter of individual wages. It may in fact compromise the economic welfare of those states—and the nation (Smith 2012). As such, and given the established literature on the returns to education, fully understanding the three points in the education pipeline most likely to have an impact on wages—graduation from high school, enrolling in any college, and earning a bachelor's degree (Monks 2000)—is paramount. In this paper we explore the third milestone, earning a bachelor's degree, as we also focus on a set of institutions not widely represented in the literature: Hispanic-Serving Institutions.

We begin by examining the earning power Latino students gain by getting a four-year college degree from the schools they are most likely to attend, HSIs. Earlier studies of labor market returns on attending college have tended to focus on college as a homogeneous treatment, making distinctions only between such broad categories as two-year and four-year schools (Kane and Rouse 1995). More recently, however, researchers have begun to untangle the heterogeneous nature of college and explore whether different types of institutions have differential returns for graduates in the labor market. Studies conducted within the last few decades have provided analytic detail by assessing the value of earning a degree from a selective college (Black and Smith 2006; Long 2010; Monks 2000), attending a selective flagship public university, and majoring in certain disciplines (Andrews et al. 2012, 2014; Hoekstra 2009).² More recent exploration of the role school selectivity plays in how college graduates fare in the labor market provides substantial contemporary results, which confirm previous findings that attending a more selective institution yields greater earnings (Dale and Krueger 2002; Zhang 2005). Barron's selectivity index is one particular measure used in this exploration. Studies using Barron's index have consistently found that students who graduate from more selective universities have higher earnings than graduates of other colleges (Brewer and Ehrenberg 1996; Brewer et al. 1999; Long 2010; Monks 2000).

Another similar avenue of exploration is the returns on attending a Historically Black College or University. Two studies to date have framed the relationship between graduating from an HBCU and individual wages. Fryer and Greenstone (2010), who utilized three large datasets (the National Longitudinal Survey of the High School Class of 1972, Baccalaureate and Beyond, and College and Beyond) to examine the impact in the labor market of graduating from an HBCU, found changes in the returns over time. In fact, from 1970 to 1990, they found a 20% decline in the relative wages of HBCU graduates. By the 1990s, this decline had in effect become a wage penalty when compared with the market outcome for those attending a traditionally White institution. Strayhorn's 2008 analysis, which used Baccalaureate and Beyond longitudinal survey data for the 1993 and 1997 cohorts, examined labor market outcomes for African Americans who graduated from HBCUs. The findings from this study revealed a moderate negative statistically significant relationship

² Reducing a university's decision to admit or deny students to both observable—standardized test scores and GPA—and unobservable variables, Dale and Krueger (2002) intuitively define selective institutions as those with higher thresholds necessary for admissions acceptance. Thus, the present study operationalized “selective flagship public universities” as the premier institutions of their respective university systems, such as the University of Texas at Austin and Texas A&M University at College Station, which correspondingly have the lowest, and therefore most selective, acceptance rates in the state of Texas.

between attending an HBCU and post-baccalaureate earnings. While these studies used data from several years ago and do not represent the definitive answer on the relationship between attending an HBCU and wages, they are helpful for future studies seeking to better understand the earning power of a college degree from other Minority-Serving Institutions (MSIs), which are postsecondary institutions that enroll a significant percentage of undergraduate minority students or that serve minority students through programs created by specific congressional legislation (U. S. Department of Education, n.d.).

Little to no current research exists on the relationship between Latinos who attend a particular type of higher education institution and their individual wages. For example, do wages differ for Latinos based on the type of four-year institution where they earn a college degree? Previous work that examined the impact attending a selective public flagship university in Texas had on wages found that White students were more likely to benefit from attending this type of institution than their Black and Latino peers (Andrews et al. 2012, 2014). Meanwhile, other studies have demonstrated that Latinos are not likely to attend a selective four-year institution in Texas and, moreover, are at least 3.5 times more likely to attend a two- or four-year HSI than a four-year non-HSI (Flores and Park 2013). While foundational to the research on wage returns to attending higher education, prior work has often utilized older datasets in which Latinos comprised a very small sample of the population and were assessed by comparing Whites to non-Whites, rather than by comparing Latinos who attend different types of institutions within the four-year sector (Black and Smith 2006; Long 2010; Monks 2000).

We set out to expand on these studies by constructing an analytic model using more recent data from a comprehensive student-level dataset from Texas. Our goal was to understand the relationship for Hispanic students between graduating from an HSI and their labor market earnings in a post-2000 economy. We specifically asked:

1. Is there a difference in Hispanic students' characteristics between HSI and non-HSI graduates in Texas?
2. What is the relationship between attending an HSI and later earnings for Hispanic college graduates in Texas?

To answer our questions, we first discuss the theoretical foundations that guided our investigation and previous research exploring labor market returns to higher education. Second, we provide more detailed information about the demographic and educational landscape of Texas, our focal state. We next present our research design, including a description of the student-level state dataset we used for our analysis, its limitations, and our analytic approach. Fourth, we present our findings, including a descriptive portrait of the data and the results from our econometric model. We end with a discussion of our findings, including recommendations for future research and a general conclusion, which highlight the challenges and the importance of access to data, as well as continued research on HSIs and on MSIs more generally.

While previous authors have provided relevant work regarding the relationship between institution type, college selectivity, and wages, much of this work has focused on cohorts graduating high school in the late 1970s with outcomes into the 1990s, with some exceptions previously noted (Black and Smith 2006; Long 2010; Monks 2000). We thus contribute to the literature in two unique ways.

Postsecondary education in the United States is becoming increasingly diverse, both in terms of the students enrolled and the types of institutions serving them, yet the impact these institutions have on their graduates' long-term outcomes, in particular on their wages, is under-examined, despite the many new data sources now available. We seek to remedy

that deficiency. Furthermore, while the research suggests that the greatest increase in the number of students attending college is among minority students, many of whom enroll in MSIs (Conrad and Gasman 2015; Flores and Park 2013), little is known about how the labor market outcomes of minority students who attend both HBCUs and HSIs compare to those who attend similarly ranked but less racially diverse institutions. This paper seeks to fill that void by examining the earnings of HSI graduates in a post-2000 economy.

Previous Literature and Conceptual Framework

From the mid-1990s to 2004, HSIs grew from being 2 to 9% of the nation's total post-secondary institutions (Li 2007). There were 409 HSIs in the United States in 2014, a 116% increase from 189 in 1995 (Excelencia in Education 2015a). Of these 409 HSIs, 81 were four-year public universities, 190 were two-year public colleges, 125 were four-year private not-for-profit institutions, and 13 were two-year private not-for-profit institutions (Excelencia in Education 2015b). HSIs are typically located in the western and the southwestern United States, with the greatest concentration in Florida, Texas, and California (Gasman et al. 2008; Harmon 2012). Because of classification requirements, the HSI designation does not mean these institutions were founded specifically to promote the education and growth of Hispanic students (Harmon 2012). Nevertheless, HSIs serve 42% of all Hispanic students, a figure that grows every year. The students attending HSIs are likely to be first-generation college students from low-income backgrounds and to have a lower level of academic preparation than those attending non-MSIs (Flores and Park 2013; Gasman et al. 2008; Harmon 2012; Institute for Higher Education Policy 2004; Li 2007). For instance, approximately 44% of Hispanic students attending HSIs in 2003 were low-income, versus 30% of those attending non-MSIs (Li 2007).

While a handful of studies have empirically examined the economic returns for attending an HBCU (e.g., Fryer and Greenstone 2010), much less is known about the returns on attending an HSI. Indeed, only a few reports are available on the economic consequences of attending an HSI, and we have found none that employs an econometric model to examine the individual return on investment of attending an HSI. What is currently known about HSIs is largely descriptive. For instance, a report commissioned by the Center for Urban Education at the University of Southern California indicates that Hispanic students in California are disproportionately enrolled in community colleges, thus the majority of the state's HSIs are two-year institutions (Malcom-Piquex et al. 2013).

However, two concurrent studies—Flores and Park (2015) and Rodríguez and Calderón Galdeano (2015)—employed a more rigorous approach to compare HSIs to non-HSIs. Both studies used propensity score matching to make more reasonable comparisons between both the students attending HSIs versus non-HSIs, and the institutions themselves. These studies suggest three principle findings. First, HSIs and non-HSIs have different student body characteristics, institutional resources, and finance structures; for instance, HSIs tend to enroll more students than non-HSIs. Second, propensity score matching on institutional characteristics yields mixed results; for example, some HSIs (specifically two-year not-for-profit institutions) did not have non-HSI matches based on institutional characters such as sector. However, when matched at the student level, HSIs and non-HSIs have comparable outcomes (Flores and Park 2015; Rodríguez and Calderón Galdeano 2015). This result provides counter evidence to previous notions that Hispanic students at HSIs underperform, at least in terms of the likelihood of graduating, when compared with

Hispanic students attending non-HSI two- and four-year colleges and universities (Dayton et al. 2004; Gastic and Nieto 2010; Laden 2004; Núñez et al. 2011; Núñez et al. 2016; Rodríguez and Calderón Galdeano 2014, 2015; Stearns et al. 2002). Still, little is known about the economic impact of attending an MSI, and an HSI more specifically (Bridges et al. 2005; Laden 2004; Rodríguez and Calderón Galdeano 2015).

In fact, much of the research on MSIs to date has dealt with the economic impact the institutions themselves have on outcomes other than student success. For instance, an Institute for Education Sciences (IES) report authored by Humphreys and Korb (2006) used data from the National Center for Education Statistics and U.S. Bureau of Labor Statistics to analyze the collective short-term economic impact HBCUs have on their regional economies. They concluded that the economic impact HBCUs have on their host communities relates to “output, value-added, labor income, and employment.” Employing a similar method of analysis, the American Indian Higher Education Consortium (AIHEC, 2000) produced a report that described the economic development efforts of the Tribal Colleges and Universities. The report argued that, despite the lack of regional and national data to confirm their effect, these colleges do in fact affect local economic development.

Importantly, neither the IES nor the AIHEC study focused on individual wage returns to graduates of these institutions. They instead used the institution as the primary unit of analysis, and linked its expenditures to returns to the economies of the host nation’s network of colleges or universities that were serving their respective minority populations. Finally, applying an investigatory focus that differed from the IES and AIHEC studies, the National Commission on Asian American and Pacific Islander Research in Education (NCAAPIRE 2014) issued a brief descriptive report that analyzed three-year-longitudinal institutional data from Asian American, Native American, and Pacific Islander Serving Institutions (AANAPISIs). This report describes the impact federally funded campus programs have on persistence, degree attainment, and transfer to four-year institutions for the low-income Asian American and Pacific Islander students enrolled at these schools. This report centers on student academic returns and thus does not consider individual economic returns in the short or long term. To date we know of no other major study on the economic impact or on the individual return on investment of attending an HSI.

Conceptual Framework

We draw our framework using an economic lens that is informed first by human capital theory, and by social and cultural capital theories. From an economic perspective, a number of empirical studies confirm that college graduates earn more than high school graduates (Card 1999; Pascarella and Terenzini 1991, 2005; Smart 1986). Indeed, Goldin and Katz (2007) have found that the correlation between education and labor market outcomes continues to increase in the United States. Although some question the extent to which education is the causal mechanism for higher earnings, many have demonstrated that, net of other factors, education has a strong impact on labor market outcomes (Hout 2012). Previous research demonstrates, for example, that students from socially or economically disadvantaged backgrounds tend to show the greatest gains from getting an advanced education—a theory known as negative selection (Brand and Xie 2010; Hout 2012; Monks 2000). In other words, negative selection suggests that, since low-income or minority students are likely to select out of higher education altogether, thus negatively impacting their earning potential, these students would have the most to gain by earning an advanced credential.

Human capital theory is one body of literature that guides our investigation of the relationship between education and earnings. It suggests that the more education and skills an individual acquires, the greater their earnings in the labor market (Becker 1964, 1967, 1993). As such, we controlled for measures of academic ability, major area of study, and years of work experience, all known to have a discernable relationship to labor market earnings (specific details on these measures appear later in this manuscript; see also Mincer 1974; Pascarella and Terenzini 2005). Research has demonstrated that an important extension of human capital theory is to condition earning functions on the location of individuals, as local prices and economic health also influence wages (Black et al. 2009).

Social and cultural capital theories add to our conceptual framework, as they provide additional insights into the factors that influence labor market outcomes. These theories suggest that information available via formal and informal networks, as well as normative structures put in place by local context, may influence earnings (Bourdieu and Passeron 1977; McDonough 1997; Perna et al. 2008). Where a student attends college is thus critical to how their degree is rewarded in the labor market. For example, factors such as secondary school context, academic preparation, and the college attended play a role in predicting the odds of college enrollment, as do the local economic and state policy contexts (Perna et al. 2008). As such, we include proxies for social and cultural capital through measures of community context and economic capacity, which several previous studies have done (Núñez and Bowers 2011; Perna 1998, 2004; Perna et al. 2008; Strayhorn 2008; Zhang 2005).

Using this framework, and given that Hispanic postsecondary students are at least 1.5 times more likely to attend two-year than four-year colleges (Flores and Park 2013), we argue that, in keeping with the negative selection theory, these students stand to benefit greatly from postsecondary education (Hout 2012). Furthermore, evidence suggests that Hispanic students graduate from HSIs at a rate comparable to those who attend non-HSIs, after controlling for similar measures of capital, as defined above (Flores and Park 2015). Therefore, we evaluate how the wages of HSI graduates compare to those of non-HSI graduates, an area that has received little scholarly attention to date, due in part to policy interest, data access, and availability.

The Texas Context

Given its sizeable number of Hispanic students and HSIs, we used data from Texas to conduct our analyses. In doing so, we acknowledge that the Texas economy—and, specifically, variations across it—have a particular relationship to labor market outcomes. In the following sections, we provide more information about both of these.

Texas Hispanic Population and HSIs

The Hispanic population in Texas is projected to grow by 31% from 2010 to 2020, which will far outpace the White population's projected growth of 2% (Fletcher and Webster 2010). As the HSI designation is determined by the percentage of Hispanic students enrolled, the number of HSIs in Texas is likely to increase over the next decade. Therefore, studying the return on investment for HSIs as compared to non-HSIs is critical to ensuring that national policy goals, and that of some grant-disbursing organizations (e.g., the Lumina Foundation), of increasing attainment are met (Lumina Foundation, n.d.).

Table 1 Public universities in Texas, by selectivity and HSI designation

More selective		Selective		Somewhat selective		Non-selective	
HSI	Institution	HSI	Institution	HSI	Institution	HSI	Institution
No	UT-Austin	No	U. North TX	No	Tarleton State U.	Yes	UT-Pan American
No	A&M-College Station	No	U. Houston	No	Texas Woman's U.	Yes	U. Houston-Downtown
No	Texas Tech	No	Stephen F Austin State U.	No	UT-Permian Basin	Yes	UT-El Paso
No	UT-Dallas	No	Sam Houston State U.	No	TX Southern U.	Yes	A&M-International
No	A&M-Galveston*	No	UT-Arlington	Yes	Sul Ross State U.	Yes	A&M-Corpus Christi
		No	Angelo State U.	Yes	A&M-Kingsville	Yes	UT-Brownsville***
		No	West TX A&M	Yes	UT-San Antonio		
		No	Lamar U.	No	UT-Tyler**		
		No	TX State U.				
		No	Prairie View A&M				
		No	A&M-Commerce				
		No	Midwestern State U.				

Selectivity rankings come from Barron's 1997 selectivity index, are used for all cohorts, and are time-invariant for the time period in this study

* Degrees from A&M-Galveston are granted through A&M College Station

** UT-Tyler is not included in the 1997 cohort due to data collection limitations

*** UT-Brownsville is not included in the 1997 and 2000 cohorts due to data collection limitations on status of institution. UT-Brownsville was in a formal partnership with Texas Southmost College, a two-year institution, until 2011, making data collection efforts on solely its four-year partner institution difficult for this analysis

In 2004, 64 HSIs in Texas (including for-profit institutions) were educating 23% of the Hispanic students attending U.S. postsecondary institutions. Texas has the second largest number of HSIs, after California, the majority of them two-year schools (Li 2007). The racial/ethnic breakdown of students attending the institutions that met the 25% Hispanic student enrollment required to be eligible for HSI designation in 2008 was 55% Hispanic, 9% African American, 27% White, and 9% Asian American.

Table 1 provides a list of the four-year public universities included in our analysis, by selectivity and HSI designation. We included all four-year public universities in Texas from which students in our cohorts graduated.³ We included only institutions that primarily awarded bachelor's degrees at the time of our analysis, so institutions that have begun since then to award BAs in addition to their primary purpose of awarding associate's degrees were excluded. At the time our cohorts graduated from high school, Texas was home to nine four-year public HSIs, all of which were classified either "non-selective" or

³ UT-Tyler is not included in the 1997 cohort, as this institution at that time only enrolled upper-division (junior and senior) students; freshmen were first admitted to UT-Tyler in 1998. UT-Brownsville is not included in the 1997 and 2000 cohort, as the database at that time did not record baccalaureate degree graduates from this institution.

“somewhat selective.”⁴ All those classified “more selective” or “selective” were non-HSIs, including the state’s two major flagship universities, The University of Texas at Austin and Texas A&M University in College Station.⁵ As noted, Hispanic students in Texas experience labor market gains from attending a state flagship university, yet these “more selective” institutions are the schools Hispanic students in Texas are the least likely to attend (Andrews et al. 2012, 2014; Flores and Park 2013). Therefore, to provide a more accurate and fair comparison of earnings for HSI and non-HSI graduates, we control for selectivity in our full models, which we discuss in more detail in the research design section.

Texas Economic Regions

Texas state agencies classify the regional economies into: (1) twelve economic regions, the classification used by the Texas Comptroller’s Office⁶; and (2) workforce development areas, the classification used by the Texas Market and Career Information program of the Texas Workforce Commission. Economic regions often are synonymous with or comprised of multiple workforce development areas. The HSIs used in our analysis are located in the following economic regions: Alamo (University of Texas at San Antonio); Coastal Bend (Texas A&M University-Corpus Christi and Texas A&M University-Kingsville); Gulf Coast (University of Houston-Downtown); South Texas Border (Texas A&M International University, University of Texas Pan-American, and University of Texas at Brownsville); and Upper Rio Grande (Sul Ross State University, and University of Texas at El Paso). With the exception of the Gulf Coast economic region, which encompasses Houston, the state’s largest city, these regional economic areas tend to support service industry jobs rather than professional jobs and to have weekly wages below the state average. The top three industries in these regions by number of employees are (1) trade, transportation, and utilities; (2) education and health services; and (3) travel and leisure. While unemployment rates vary among regions and are occasionally above state averages, the average weekly wages in these regions are well below the state average (Texas Workforce Commission 2015). Thus, it is likely that regional differences across economic regions will also contribute to labor market outcomes. We account for these differences using economic region fixed effects, as will be discussed in more detail in our research design.

Research Design

Our research design is divided into two main sections, one that describes the data sources used for this paper, and one that describes the analytic approach we used to answer our research questions. The description of the data sources includes a section on how we defined post-graduation earnings, our inclusion criteria, and some limitations of the data.

⁴ UT-Permian Basin is not flagged as an HSI as it did not meet the 25% threshold in 1997. Furthermore, we do not include Brazosport College, Midland College, or South Texas College as HSIs; although these institutions meet the 25% threshold, they primarily award associate degrees.

⁵ Selectivity rankings come from Barron’s 1997 index and are time-invariant in cohort analyses.

⁶ For a map of the Texas economic regions, see https://texaspolitics.utexas.edu/archive/html/pec/features/0302_02/regmap.html.

Data Sources

Data for this paper came from the Education Research Center housed at the University of Texas at Dallas, which manages student-level data from the Texas Education Agency, the Texas Higher Education Coordinating Board, and the Texas Workforce Commission. Using a de-identified student indicator, we were able to link these data together and to include information on students from high school through college and on into the workforce.

Our independent variable of interest—whether the school a student graduated from was an HSI—was defined using the federal HSI designation, which includes any higher education institution that is accredited, grants degrees, and whose full-time-equivalent undergraduate enrollment is at least 25% Hispanic (Santiago and Andrade 2010; U.S. Department of Education 2009, 2013). We also acknowledged recent work that has begun to examine the heterogeneity within HSIs and to properly question whether the HSI enrollment criteria of 25% or more accurately represents the variation within the HSI institutional community. Generally, federal HSI designation meets three identity criteria: (1) the institution is located in a highly populated Hispanic area and thus is likely to qualify demographically to enroll a significant Hispanic student population; (2) the institution has a stated “mission to serve” Hispanic students; and (3) the institution has executed its mission to serve by formally applying for federal HSI designation (Núñez and Bowers 2011; Núñez et al. 2011; Núñez et al. 2016). The institutions in our sample meet at least two of these three criteria. For example, most of the institutions in our sample have formally received federal funding from the DHSI program, have an explicit mission to serve Latino students, or has recently met the 25% full-time Hispanic enrollment criteria through demographic changes regarding student enrollment in an area. We did not require all institutions to meet all three criteria as the federal government does not provide comprehensive yearly data on all DHSI applicants and recipients in public format.

To isolate the relationship more clearly between graduating from an HSI and labor market earnings, we controlled for a number of factors also plausibly related to both graduating from an HSI and eventual earnings:

1. *Student background characteristics [S]* sex (coded as 1 for male) and limited English proficiency status. English learner status is coded as 1 for a student having been designated by their K-12 school district at the time of high school graduation. We note that the English learner designation in 12th grade is distinct from being so identified in earlier grades;⁷
2. *High school academic preparation [ACAD]* taking an Advanced Placement or International Baccalaureate course (coded as 1 for taken), taking a trigonometry course (coded as 1 for taken), state mathematics exam score (a linear measure), and enrolling at a college while still in high school (coded as 1 for students who dual enrolled);
3. *Community context [COMM]* high school pupil-teacher ratio (a simple ratio), high school enrollment (logged), high school minority percentage (a percentage of Hispanic and Black students), high school per-pupil expenditures (logged), urbanicity (as defined by the U.S. Census), county unemployment rate (a percentage), and a binary indicator of whether the student’s high school was within 25 miles of a postsecondary institution;

⁷ For a more detailed description of the identification of English learners in Texas at the point of classification, see Flores et al. (2012).

4. *Economic capacity [ECON]* a binary indicator for free or reduced-price lunch status (FRL) in high school (a measure of economic disadvantage) and a binary indicator for whether the student worked while still in high school;⁸
5. *Years of experience [EXPER]* defined as the number of calendar years following graduation from high school in which an individual earned at least \$100 in at least one quarter of the year;
6. *Major area [MAJ]* included in the model as fixed effects, defined by the two-digit Classification of Instructional Programs for the program from which an individual graduated (all graduates regardless of major area are included in the analysis); and
7. *Job location [LOC]* included in the model as fixed effects for state of Texas economic regions.

Defining Earnings

For our dependent variable—labor market return as represented by wages—data were available from the Texas Workforce Commission, they were reported quarterly, and there were separate records for individuals reporting income from more than one source. First we determined the total earnings for individuals reporting more than one income source in a given quarter to achieve a quarterly earnings figure. Then we defined annual earnings as the total earnings reported in a calendar year (four-quarter) cycle, beginning in January ten years after high school graduation. Thus, earnings for the 1997 cohort came from 2007, earnings for the 2000 cohort came from 2010, and earnings for the 2002 cohort came from 2012. We selected this timeframe based on work by Mincer (1974), who showed that the return to schooling could be underestimated if measured before enough time had passed since graduation. Mincer and others have suggested specifically that using earnings data from an individual's early twenties can be problematic, as the return to a postsecondary education may not yet have been realized in the labor market (Andrews et al. 2012, 2014; Hoekstra 2009; Mincer 1974). As we investigated each cohort separately and were interested in the difference in earnings between HSI and non-HSI graduates, we did not adjust wage figures for inflation in our models; however, we do present constant, CPI-adjusted 2002 dollars in our descriptive portraits. Finally, due to the distribution of the earnings data, we used logged wages in our analytic model.

Sample Inclusion Criteria

Given the limitations associated with merging three independent data sources, we included three cohorts of Hispanic students who graduated from public high schools in Texas in the spring of 1997, 2000, and 2002, and analyzed each cohort separately. Each year represents a cohort that enrolled in college prior to a particular policy change in Texas higher education, and that meets the required six-year graduation rate for the last year of data available to us at the time of our analysis. For example, 1997 is the year before the Texas Top Ten Percent Plan was fully implemented; 2000 is the year preceding implementation of the in-state resident tuition policy, House Bill 1403, and a new influx of state financial

⁸ Unfortunately, our data do not include financial aid information for respondents so we are not able to measure issues of affordability. The analysis focuses instead on the level of economic disadvantage.

aid; and, finally, 2002 is the year before Texas colleges and universities deregulated tuition, which made Texas tuition significantly higher than in other states (Flores and Shepherd 2014). Thus, we used these cohorts as a robustness check to determine whether our findings were consistent across multiple cohorts that corresponded with significant shifts in Texas higher education policy. To be included in the cohorts, individuals must have (1) enrolled in a public four-year university in Texas in the fall immediately following high school graduation (transfer students were not included in this analysis); (2) completed a college degree within six years at the same institution they started at; (3) had no missing data on any of the covariates used in the analysis; and (4) showed earnings of at least \$100 in all four quarters in the calendar year (four-quarter) cycle beginning in January ten years after high school graduation. Unlike other studies, we did not restrict our sample to males; however, we followed conventions similar to those used by Andrews et al. (2012, 2014) and Hoekstra (2009), who also used similar data.

Data Limitations

These data are subject to limitations in terms of the availability of a more comprehensive set of variables that may be available in other datasets, such as parental education and income, and generational status in the U.S. We note, however, that our measures for student demographic characteristics and pre-college preparation and economic status are proxies for these measures, a strategy employed by previous work in economics (Black and Smith 2006). The data also do not contain information on students who attended private schools or on the earnings of individuals working outside of Texas. However, we emphasize the opportunity made possible by the Texas dataset that allowed us to (1) access wage records not available nationally, (2) provide a longitudinal perspective on multiple cohorts across various economic periods in the U.S. and Texas, and (3) link student characteristics and academic preparation as well as high school, postsecondary, and community contexts to wage records in ways not possible with other datasets. Thus, while no dataset is perfect, we argue that it is worth investigating the individual-level returns to wages that result from attending HSIs, especially since they have not previously been evaluated in this manner.

Analytic Approach

To answer the first research question, we compiled a detailed descriptive portrait that compares Hispanic college graduates who attended HSIs to those who attended non-HSIs, with a focus on labor market earnings. In so doing, we examined the earnings data, the characteristics of graduates, and where these individuals were working. We conducted this investigation using a series of descriptive tables that will be discussed in the following section.

Hispanic student earnings ten years after college enrollment are a function of demographics, pre-college academic preparation, community context, economic context, years of experience, major area, physical location, and whether or not the student attend an HSI, which is formally modeled as:

$$\log(\text{earnings}) = \alpha + \beta(\text{HSI}) + \theta(S) + \delta(\text{ACAD}) + \zeta(\text{COMM}) + \lambda(\text{ECON}) + \pi(\text{EXPER}) + \text{MAJ} + \text{LOC} + \varepsilon \quad (1)$$

Under this specification, β captures the net relationship between graduating from an HSI and earnings, controlling for vectors S , $ACAD$, $COMM$, $ECON$, and $EXPER$, as identified above, as well as a set of fixed effects (included as dummy variables) for MAJ and LOC ; ε is an individual specific error term. By including the MAJ and LOC fixed effects, we account for the fact that students with different college majors and the economic regions in which students are working are likely related to earnings. Earnings are logged due to their distribution and in accordance with previous literature (e.g., Cellini and Chaudhary 2012; Dagdar and Weiss 2012).

As previous research has indicated that attending a more selective, better-resourced institution has a positive impact on earnings, we performed an additional iteration of the model by including indicators for Barron's selectivity index (a single indicator that equals 1 for the more selective and somewhat selective institutions and 0 otherwise), the percentage of tenured faculty members at the institution, the faculty-to-student ratio, the number of full-time-equivalent students (logged), and the number of state appropriations for students (logged). We did this to provide a more reasonable comparison between the outcomes for those graduating from HSIs and non-HSIs, as there currently are no HSIs in the top Barron categories. In essence, we controlled for selectivity and institutional capacity, thus allowing for a more precise estimate of any effect of attending an HSI on labor market outcomes for Hispanic students.

This approach builds on earlier studies that investigated the impact postsecondary education has on labor market outcomes (Andrews et al. 2012, 2014; Hoekstra 2009; Strayhorn 2008). As noted by Kaymak (2009), however, without proper statistical controls and carefully chosen comparison groups, it is difficult to identify the relationship between education and labor market outcomes, due to the spurious relationship between academic ability, college selectivity, and post-graduation earnings. As such, we were careful to construct our model with a number of controls designed to capture human and social capital factors, and then restricted our sample in a manner that provided a more accurate comparison between institutions. We now offer a discussion of the results gleaned from these approaches.

Results

We begin with a descriptive portrait of Hispanic students who have graduated from HSIs and non-HSIs, and their average post-graduation earnings, as motivation for the results from our analytic model. Tables 2, 3, and 4 provide key descriptive statistics, such as mean and standard deviation on the primary variables of the analysis, organized by the 1997 ($N = 2,106$), 2000 ($N = 2,781$), and 2002 ($N = 3,196$) cohort years. We present them in aggregated totals by year, and also broken out by institution type (i.e., HSI or non-HSI); the far-right column lists the difference between the types of institutions. Three main themes emerge from this table, which we discuss below.

First, it is worth noting that, while the overall samples remain relatively consistent in terms of gender breakdown, with fewer males than females, there is a gender shift between HSIs and non-HSIs. More specifically, approximately 40% of each cohort is male: 39.65% in 1997, 39.23% in 2000, and 40.05% in 2002. However, the proportion of Hispanic male graduates is greater at HSIs (39.8%) than at non-HSIs (37.62%) only in the 1997 cohort. In 2000 and 2002, total HSI graduates ($N = 1,323$ and $N = 1,636$) and non-HSI graduates ($N = 1,458$, and $N = 1,560$) included 3.75 and 2.41% more males than females, respectively. As for English learner status, the percentage of students classified as limited English

A full list of schools used in this analysis, by year of inclusion and HSI status, is provided in Table 1. *LEP* refers to limited English proficiency, *AP* refers to advanced placement, *IB* refers to international baccalaureate, and *FRL* refers to free and reduced-price lunch, a measure of economic disadvantage.

proficient dropped across all cohorts and across HSI designation, which signals a potentially more selective cohort over time. The data show that the percentage of students classified as limited English proficient dropped from 3.38% in 1997 to 1.50% in 2000, and to 0.61% in 2002 at HSIs, and at non-HSIs it dropped from 0.64% in 1997 to 0.48% in 2000, and to 0.38% in 2002.

Second, wage differentials and economic disadvantage between institution types are striking. For instance, in the 1997 cohort, graduates of non-HSIs had a \$6,227.50 average wage premium over HSI graduates; the number fell to \$5,375.13 for the 2000 cohort but increased to \$7,667.13 for the 2002 cohort (all expressed in constant, CPI-adjusted 2002 dollars). This widening wage gap is depicted by institution type in Fig. 1, and is consistent with the literature on wage gap differentials (e.g., Monks 2000; Strayhorn 2008). Along the same lines, the percentage of students classified as economically disadvantaged (those students who receive free or reduced priced lunch) grew in each cohort year, as did the gap by institution type: 1997—45.98% at HSIs and 23.02% at non-HSIs; 2000—51.85% at HSIs and 28.05% at non-HSIs; and 2002—54.89% at HSIs and 29.94% at non-HSIs. Put differently, the proportion of HSI graduates who were classified as economically disadvantaged was nearly double that of non-HSI graduates in every cohort.

Third, in terms of academic preparation, we found that graduates of both HSIs and non-HSIs were better prepared for college entry over time for each cohort year; however, HSI graduates remained slightly less prepared to participate in rigorous academic coursework at the postsecondary level than graduates of non-HSIs. Participation in AP/IB courses at HSIs was 34.56% in 1997, 68.32% in 2000, and 65.65% in 2002; at non-HSIs it was 48.59% in 1997, 71.87% in 2000, and 75.13% in 2002. In short, HSI graduates were enrolled in advanced coursework at a rate 14.03% points lower than non-HSIs in 1997, but only 3.49 points lower in 2000 and 9.48% points lower in 2002. The gap in the percentage of graduates from HSIs and non-HSIs who participated in dual-enrollment programs while still in high school was 7.29% points in 1997, but there was nearly no difference in 2002, a mere 0.67% points.

Econometric Model Results

Table 5 presents regression results for our cohorts. Model 1 for each cohort is the full sample, including the main array of control variables; Model 2 adds the postsecondary controls, including selectivity. All models include the full array of covariates that account for differences in human capital, social capital, and location of employment (Texas

economic region) ten years after graduating from high school. As our outcome variable is logged, the raw coefficients roughly represent the percentage change in earnings for a unit change for a particular independent variable, holding the others constant. More specifically, the raw coefficient for HSI (a dichotomous indicator) can roughly be interpreted as the percentage change in earnings for Hispanic graduates of HSIs compared to Hispanic graduates of non-HSIs. For added precision, however, we discuss our main findings in text using the semi-elastic calculation [$100 * (\exp(\text{Bhat}) - 1)$]; in doing so, we are able to provide the exact difference in the percentage change in wages between graduates of HSIs and non-HSIs (Wooldridge, 2013).

Across all cohorts, Model 1 reveals a negative and statistically significant relationship between graduating from an HSI and earnings. More specifically, Model 1 shows that Hispanic graduates of HSIs have annual wages 6.85, 6.29, and 4.59% lower than Hispanic graduates of non-HSIs, for the 1997, 2002, and 2002 cohorts, respectively, after accounting for other factors in the model. We note that males have higher earnings than females, and that students who are better prepared in high school (at least as reflected in math exam scores) earn more, as do students with more work experience. Thus, while human, social, and economic capital all play a role in earnings, there appears to be a persistent penalty for attending an HSI—at least before also considering postsecondary context.

In Model 2, however, there is no statistically significant difference between the earnings of HSI graduates and non-HSI graduates—in other words, Hispanic HSI graduates earned just as much as non-HSI graduates from institutions that are similar in terms of selectivity and resources. Although males continue to earn more than females, as do students with greater pre-college academic preparation and those with more years of work experience, we fail to identify a penalty for attending an HSI when taking into account other differences in postsecondary context. In other words, we have no reason to suggest that attending an HSI has a specific discernable influence on how much students earn after graduation.

Discussion

This paper sheds further light on HSIs, which are a growing segment of American higher education, and the population of students these institutions serve. We find that differences exist between Hispanics who graduate from HSIs and those from non-HSIs in terms of post-graduation earnings, as well as pre-college academic preparation and contextual factors, both of which are known to influence earnings. However, we demonstrate that differences in earnings between Hispanic students who graduate from HSIs and those from

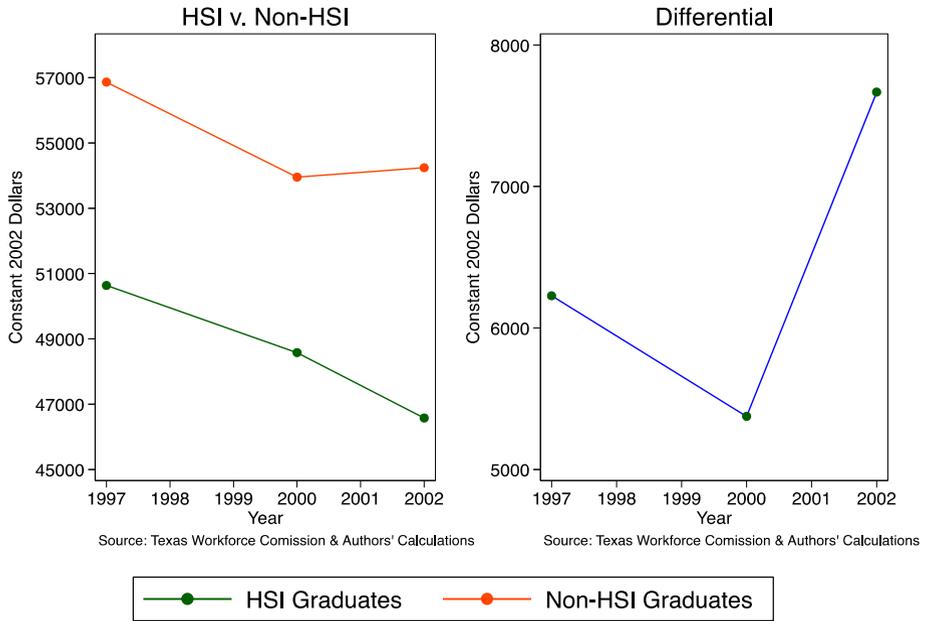

Fig. 1 Earnings by HSI designation and differential

non-HSIs are driven by selectivity and institutional resources rather than HSI designation. We found no difference in wages when comparing graduates of HSIs and non-HSIs that are similarly selective and similarly resourced, after controlling for our measures of human and social capital and the region of Texas where the graduates were employed ten years after finishing high school.

This finding is important, as HSIs are often criticized for having lower graduation rates and, by extension, lower returns on investment for those attending these institutions (Fryer and Greenstone 2010; Riley 2010; Vedder 2010). Previous research has provided evidence that, after controlling for student and institutional characteristics, Hispanic students graduate from HSIs at the same rate as from non-HSIs (Flores and Park 2015). This analysis suggests similar outcomes in regard to labor market outcomes: Hispanic students graduating from HSIs have earnings comparable to those who graduate from non-HSIs, after accounting for selectivity and institutional resources. More selective institutions, by definition, have more restricted admissions policies and enroll a more academically prepared body of students. Similarly, better-resourced institutions are able to provide additional opportunities for students. Analyses that compare HSIs to non-HSIs without accounting for the enormous role selectivity and resources at play should at least acknowledge the important role of selection bias in interpreting such results. Proper comparison groups, when available, are the most accurate way to present research. If such data are not available, which is a common limitation in many analyses, we recommend acknowledging this limitation and the associated implications of policy recommendations based on the limited data.

Our analysis does not suggest that Hispanic students should not attend selective institutions. They instead illuminate the need to account for key elements in order to reduce selection bias in the analysis of outcomes by institutional selectivity. In other words,

A full list of schools used in this analysis, by year of inclusion and HSI status, is provided in Table 1. *LEP* refers to limited english proficiency, *AP* refers to advanced placement, *IB* refers to international baccalaureate, and *FRL* refers to free and reduced-price lunch.

*** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$. Model 1 includes the full array of pre-college characteristics; Model 2 adds postsecondary controls, including selectivity.

Hispanic HSI graduates working in the Texas labor market are earning wages similar to those of their Hispanic peers who attended similarly ranked non-HSIs. This fact is even more relevant when considering that the majority of Hispanic students in Texas enroll at non-selective or moderately selective institutions, and that HSIs tend to be funded at only 66 cents for every dollar spent at all other postsecondary institutions (Hispanic Association of Colleges and Universities, 2013).

Directions for Future Research

This study is one of the first to examine how Hispanic students graduating from HSIs fare in the labor market as compared to non-HSI graduates in a post-2000 economy. As noted, while the chosen dataset is rich, provides for longitudinal tracking of students, and is from a state with a large number of HSIs and Hispanic postsecondary students, studies conducted in other contexts would help tell a more complete story of the labor market returns to attending an HSI across the country. For instance, similar studies could be conducted in California, New York, and Florida, all of which have sizeable Hispanic populations and databases similar to those in Texas. Furthermore, additional research that examines outcomes across state boundaries is imperative if we are to be able to tell a complete story of the role education plays in the well-being of individuals in the United States. The State Higher Education Executive Officers have developed reports that show partnerships beginning within and across states that are linking data between sectors (K-16) and some states (Garcia and L'Orange 2010). Researchers should take time to familiarize themselves with the possibilities, limitations, and priorities of state governments in order to gain a clear understanding of whether underserved students and institutions are part of the current research agendas.

Conclusion

While we have laid a strong foundation on which to build additional studies, there is still not enough research on the effect HSIs, and MSIs more generally, have on outcomes such as labor market returns and graduate degree acquisition, and how these effects vary by

context. For example, how does the effect of attending an HSI vary by state? What role do HSIs in Texas play in the acquisition of graduate degrees, and what effect do graduate degrees have on labor market outcomes? Finding answers to these questions and others will only be possible if there is more high-quality data available and better access to it. U.S. higher education is experiencing profound changes related to demography, technology, costs, and outcomes. As policies are suggested, implemented, and retracted, we recommend that giving precise and sustained attention to the changing student demography of U.S. higher education be a key priority for all states. A lack of responsiveness to the evolving national demographics will be not only costly but also counter to the goal of improving educational opportunity for reasons of civic and social justice, and for the economic survival of states and institutions. The changing demographics in many of our states and institutions will require us to make a unified effort to provide educational opportunity for all. We thus urge state agencies, funding organizations, and other scholars to appreciate the importance and research power of state education data systems, as we have outlined both here and in a 2015 special issue of *Educational Evaluation and Policy Analysis*. Only continued research using sophisticated datasets, as well as funding to support the research work, will enable us to gain a full understanding of the role played by HSIs in the nation's higher education system, and thus allow us to offer the best possible recommendations for state and federal policy that will improve educational outcomes for *all* students.

Acknowledgements The authors would like to thank the University of Pennsylvania Center for Minority Serving Institutions, the Educational Testing Service, the University of Texas at Dallas Education Research Center, and New York University for their assistance and support of this study.
